RESEARCH LETTER

COVID-19 and Excess All-Cause Mortality in the US and 18 Comparison Countries

The US has experienced more deaths from coronavirus disease 2019 (COVID-19) than any other country and has one of the highest cumulative per capita death rates.^{1,2} An unanswered question is to what extent high US mortality was driven by the early surge of cases prior to improvements in prevention and patient management vs a poor longer-term response.³ We compared US COVID-19 deaths and excess all-cause mortality in 2020 (vs 2015-2019) to that of 18 countries with diverse COVID-19 responses.

Methods | We compared the US with Organisation for Economic Co-operation and Development countries with populations exceeding 5 million and greater than \$25 000 per capita gross domestic product. For each country, we calcu-

lated the COVID-19 per capita mortality rate and grouped countries by mortality: (1) low (COVID-19 deaths, <5/100 000), (2) moderate (5-25/100 000), and (3) high (>25/100 000).¹ We used Poisson regression for comparisons across countries.

We calculated the difference in COVID-19 deaths between each country and the US through September 19, 2020 (week 38) under 3 scenarios: if the US had a comparable per capita COVID-19 mortality rate to each country from the start of the pandemic (February 13) or if the US mortality rate became comparable to other countries beginning May 10 or June 7, to allow lag time for policy interventions.³ (See the Supplement for formulas.)

We also considered all-cause mortality per capita for countries with publicly available data through July 25, 2020 (week 30). This measure is robust to country-level differences in COVID-19 death coding and captures indirect pandemic effects. We estimated excess all-cause mortality (the difference between mean 2020 deaths and deaths in corresponding weeks of 2015-2019) for each country and the US,

Table 1. COVID-19 Mortality in the US Compared With That of Other Countries^a

Country	Date COVID-19 cases surpassed 1 per million	COVID-19 deaths per 100 000			Excess US COVID-19 deaths (% of reported deaths)		
		Since the start of the pandemic	Since May 10, 2020	Since June 7, 2020	Since the start of the pandemic	Since May 10, 2020	Since June 7, 2020
Low mortality (COVID-19 deaths, <5/100 000)							
South Korea	2/20/20	0.7	0.2	0.2	196 161 (99)	120 625 (61)	88 771 (45)

United States	3/7/20	60.3	36.9	27.2			

^a Data on coronavirus disease 2019 (COVID-19) deaths are from February 13, 2020, through September 19, 2020 (n = 198 589 US deaths). In columns 4-6, due to large sample sizes, all mortality rates are statistically significantly different from the corresponding US mortality rates ($P < .001$). Scenarios in the last 3 columns assume that compared with the country in a given row,

(A) the US had a comparable cumulative mortality rate; (B) the US mortality rate was unchanged until May 10 (n = 77 180 deaths), when it became comparable to the other country's death rate; and (C) the US mortality rate was unchanged until June 7 (n = 109 143 deaths), when it became comparable to the other country's death rate.

Table 2. Excess All-Cause Mortality in the US Compared With That in Other Countries^a

Country	Excess all-cause mortality per 100 000			Excess US deaths from all causes (% of reported deaths)		
	Since the start of the pandemic	Since May 10, 2020	Since June 7, 2020	Since the start of the pandemic	Since May 10, 2020	Since June 7, 2020
Moderate mortality (COVID-19 deaths, 5-25/100 000)						
Norway	-2.6	-4.3	-2.1	235 610 (100)	102 598 (44)	63 952 (27)

Belgium	67.8	-4.6	-6.4	12 638 (5)	102 598 (44)	63 952 (27)
United Kingdom	94.5	13.7	-1.2	-75 196 (-32)	57 659 (24)	63 952 (27)
Spain	102.2	2.1	1.8	-100 768 (-43)	95 784 (41)	57 948 (25)
United States	71.6	31.2	19.4			

^a Data on deaths are through July 25, 2020 (week 30, n = 235 610 excess US deaths compared with 145 546 reported COVID-19 deaths). Countries lacking publicly available all-cause mortality data through this time are omitted. Excess deaths were estimated by week, compared with 2015-2019, beginning when a country surpassed 1 COVID-19 case per million population. In columns 3-5, due to large sample sizes, all mortality rates are statistically significantly different from the corresponding US mortality rates ($P < .001$). Scenarios in the last 3 columns assume that compared with the country in a given row: (A)

the US had a comparable cumulative mortality rate; (B) the US excess all-cause mortality rate was unchanged until May 10 (week 20, n = 133 012 deaths), when it became comparable to the other country's death rate; and (C) the US excess all-cause mortality rate was unchanged until June 7 (week 24, n = 171 659 deaths), when it became comparable to the other country's death rate. Totals are truncated to avoid exceeding US estimated deaths. Due to reporting lags, these data include less follow-up time than Table 1, which in some cases produces lower cumulative death rates.

compared rates across countries using Poisson regression with country and week fixed effects (Supplement), and estimated the difference in excess all-cause mortality between each country and the US as described above. We used R software (version 4.0.2) for all analyses.

Results | On September 19, 2020, the US reported a total of 198 589 COVID-19 deaths (60.3/100 000), higher than countries with low and moderate COVID-19 mortality but comparable with high-mortality countries (Table 1). For instance, Australia (low mortality) had 3.3 deaths per 100 000 and Canada (moderate mortality) had 24.6 per 100 000. Conversely, Italy had 59.1 COVID-19 deaths per 100 000; Belgium had 86.8 per 100 000. If the US death rates were comparable to Australia, the US would have had 187 661 fewer COVID-19 deaths (94% of reported deaths), and if comparable with Canada, 117 622 fewer deaths (59%).

While the US had a lower COVID-19 mortality rate than high-mortality countries during the early spring, after May 10, all 6 high-mortality countries had fewer deaths per 100 000 than the US. For instance, between May 10 and September 19, 2020, Italy's death rate was 9.1/100 000 while the US's rate was 36.9/100 000. If the US had comparable death rates with most high-mortality countries beginning May 10, it would have had 44 210 to 104 177 fewer deaths (22%-52%) (Table 1). If the US had comparable death rates beginning June 7, it would have had 28% to 43% fewer reported deaths (as a percentage overall).

In the 14 countries with all-cause mortality data, the patterns found for COVID-19-specific deaths were similar for excess all-cause mortality (Table 2). In countries with moderate COVID-19 mortality, excess all-cause mortality remained negligible throughout the pandemic. In countries with high COVID-19 mortality, excess all-cause mortality reached as high as 102.1/100 000 in Spain, while in the US it was 71.6/100 000. However, since May 10 and June 7, excess all-cause mortality was higher in the US than in all high-mortality countries (Table 2).

Discussion | Compared with other countries, the US experienced high COVID-19-associated mortality and excess all-cause mortality into September 2020. After the first peak in early spring, US death rates from COVID-19 and from all causes remained higher than even countries with high COVID-19 mortality. This may have been a result of several factors, including weak public health infrastructure and a decentralized, inconsistent US response to the pandemic.^{4,5}

Limitations of this analysis include differences in mortality risk: the US population is younger but has more comorbidities compared with the other countries.⁶ In addition, since late August death rates have increased in several countries, and how mortality will compare with the US throughout fall remains unknown.

Pediatric Magnet Ingestions After Federal Rule Changes, 2009-2019

Magnet ingestions among children have become a serious health risk after the 2009 introduction of high-powered, rare-earth magnets, commercially sold as small (3- to 6-mm) recreational objects.^{1,2} These neodymium magnets are 5 to 10 times more powerful than traditional ferrite magnets and are sold as sets for entertainment and toys (eg, Bucky Balls building sets, jewelry kits, spinning toys).³ Ingestion of multiple magnets, or a magnet with a metal object, can result in bowel obstruction, perforation, and death when magnets attach through bowel walls.⁴ After reports of pediatric injuries and deaths related to ingested neodymium magnets, the Consumer Product Safety Commission (CPSC) initiated campaigns to limit sales in 2012 with voluntary recalls and safety standards.⁵ Other CPSC efforts included awareness campaigns, legislative advocacy, and lawsuits.¹ In October 2014, the CPSC published its final rule, Safety Standard for Magnet Sets, prohibiting sales of these small high-powered magnet sets.³ In November 2016, this rule was legally remanded by the US Court of Appeals 10th Circuit after being challenged by Zen Magnets LLC, resulting in a resurgence of these magnets on the market.⁶ This study examined trends in US emergency department (ED) visits for pediatric magnet ingestions over the period of the changes in federal regulations.

Methods | Data from the National Electronic Injury Surveillance System (NEISS), a national sample of US injury-related ED visits, were obtained for January 1, 2009, through December 31, 2019. Magnet ingestions were identified for children aged 17 years or younger with NEISS diagnosis codes of ingested object (41) or aspirated object (42). Only narratives with the key word *magnet* were included. We used US Census data, NEISS sample weights, and clusters to calculate age-specific weighted rates of ED visits for ingestions per 100 000 persons of the population. An interrupted time-series analysis using linear regression modeling examined trends during 3 periods: (1) 2009-2012, before CPSC involvement; (2) 2013-2016, during the CPSC federal rule (including increasing CPSC regulations); and (3) 2017-2019, after the CPSC rule was vacated. Mean ED visit rates for each period and slope changes between periods were calculated. Analysis of variance was used to compare demographics. A 2-sided $P < .05$ was considered significant. Data were analyzed with SAS version 9.3 (SAS Institute Inc) using SURVEY-FREQ, SURVEYREG, and SURVEYLOGISTIC, and R for regression analyses (2020; R Foundation). This study was deemed exempt by the Partners Healthcare Institutional Review Board.

Results | A total of 36 701 ED visits were identified for ingested or aspirated objects; 1421 met criteria for magnet
